Introduction
The goal of this project was to create a board game that, by engaging student interest in the legal and ethical issues surrounding genetic technologies, would increase their comprehension and retention of lesson material. A lecture on ethical and genetic technologies was presented to two 10th grade biology classes and two 12th grade AP biology classes.

A pre-posttest assessment method was employed to determine the impact of the board game on student comprehension and retention. Pre-test scores of the experimental group increased by a greater amount than that of the control group, implying that the students who played the board game experienced an educational benefit beyond the standard lecture and review type lesson. Student feedback collected during formal (high school research participants) and informal settings (college peers) was enthusiastic and supported the hypothesis that a board game would encourage deeper engagement and interest.

Significantly higher test scores coupled with positive reviews from both college and high school students show that the game achieved its primary and secondary goals.

Materials and Methods
A pre-posttest method was used to assess the success of this board game as an instruction-enhancing tool. A 30 point test was created to measure student performance before and after the two day unit. The test assessed students' understanding of vocabulary words and application of facts and concepts. (Fig. 1) Scores were then analyzed using Fisher's Analysis of Variance (ANOVA).

![Figure 1. Sample Pre/Post test questions](image)

Preposttest scores were compared using Fisher's Analysis of Variance (ANOVA) on Minitab. As a means of control, pretest scores for both pretest groups were evaluated against each other. This analysis showed no significant difference (p-value = 0.92) between the pretest scores of the two groups, verifying that both classes started with the same basic knowledge. (Table 1)

The main posttest scores were compared to the experimental group. A significant difference (p-value = 0.001) was seen between pre and posttest scores of the control group and also between pre and posttest scores of the experimental group (p-value <0.001). Both classes did have significantly improved posttest scores demonstrating learning did occur in both classrooms. (Table 2)

Finally, a significant difference (p-value = 0.019) between posttest scores of both groups indicate the amount of learning experienced by the experimental group is significantly different from that of the control group. (Table 1)

### Game Play

Game play was designed to be simple—possible to learn the rules and play in 45 minutes—but also incorporate proven methods for improving student retention and motivation. Students play on teams that function as their own society. The ultimate goal of game play is for students to apply information from the lesson plan to trivia questions (serious and humorous) and prompt discussion of ethical considerations.

The game board itself has two separate tracks, one follows the route of the educational material, while the other is cut through the center. These two paths have an unequal proportion of opportunities to land on spaces that require the application of lesson plan information to ethical scenarios. The central path provides an increased chance to land on these Ethics card prompts. A team must discuss and create “laws” for a total of four Ethics cards in order to win. This makes the central path optimal. But in order to be granted access to the central path, teams must land exactly on a Trivia card space and answer the question correctly.

As mentioned previously, the game consists of three card types. Trivia cards are intended to reinforce scientific facts and concepts from the lesson plans and correlate to the knowledge and comprehension levels of Bloom’s Taxonomy. (Figure 3a)

The second card type, Karma cards, work the same as “Chance” cards in the board game Monopoly. These cards have two parts, a humorous story that is meant to convey new information not included in the lesson, and a second part with directions for game play. This card type adds an element of luck to the game; creates more opportunities for teams to encounter Trivia card spaces, and introduces students to possible consequences of developing genetic technologies. (Figure 3b)

The third type of card, the Ethics card, gives players the opportunity to choose what they will and will not allow in their society. Each Ethics card presents a situation prompt and the team must work together to reach a decision or ruling. Each discussion prompt is phrased to encourage thinking from the perspective of the society's ethical reasoning.

### Results

Preposttest testing is designed to assess academic progress during an instructional unit. Preposttest results establish a baseline of student knowledge for comparison with later posttest results. Graphical representation of each assessment (Figure 4) illustrates that the mean posttest score for the game group is higher than that of the control group. Based on these results, it can be concluded that significantly more learning— as measured by an assessment of understanding and retention of material— occurred in the class that played the board game.

![Figure 4. The mean pretest scores for both groups are not significantly different as seen in this figure and by the p-values reported below. The mean posttest scores for both groups are significantly different according to the p-values reported below. The experimental group had a mean posttest score significantly higher than that of the control group.](image)

### Conclusions

Both classrooms experienced learning— as shown by increased posttest scores for both treatments— however the pre-posttest scores that were increased are of a greater amount of learning. Improvement of test scores was significantly greater in the experimental group, suggesting an added benefit from playing the board game in place of a verbal review. The validity of these findings is supported by the pre-posttest scores not showing significant difference between the two groups. This indicates the groups were equivalent before the unit began and any observed test scores is more likely due to the lesson plan and type of pedagogy used for review rather than chance.

These results support a conclusion that the board game created a deeper understanding of the material. One teaching strategy that may account for the board game’s influence is adapting to multiple learning styles. By providing students with visual, auditory, and kinesthetic cues this type of review satisfies learners of every type while a verbal review does not (Piaget 1958).

Bloom’s Taxonomy is a model for creating measurable lesson objectives. For this research the pre/posttest and game cards were written to encourage thinking at all levels of the taxonomy. Analysis of specific test questions indicates that students from the control group could correctly recall definitions or facts from the lecture; however, they faced questions requiring the application of this knowledge to new situations. The experimental group showed the ability to think critically and apply facts, thus operating at a higher cognitive domain (Bloom 1956).

Many instructors are just as frustrated by educational games that do not actively engage students as they are by entertaining games that have no educational value (Chimeno 2009). By utilizing both educational and motivation strategies, the design of this game can address both of these problems. Integrating the type of teaching tool with possible future technology, into the classroom may lead to a more enduring understanding of subject matter. Future testing for this board game would include large samples sizes and delayed post testing to see if the same level of performance is still possible several weeks after playing the game.
